Global Wealth  
Databook 2012

## Preface

This is now the third edition of the Credit Suisse Global Wealth Databook – an in-depth project that offers investors the most comprehensive study of world wealth, and which remains the only study that analyzes the wealth of all the world's 4.6 billion adults.

Research for the Credit Suisse Global Wealth Databook has been undertaken on behalf of the Credit Suisse Research Institute by Professors Anthony Shorrocks and Jim Davies, recognized authorities on this topic, and the architects and principal authors of "Personal Wealth from a Global Perspective," Oxford University Press, 2008. Rodrigo Lluberas has also been a very significant contributor to the project.

The aim of the Credit Suisse Global Wealth project is to provide the best available estimates of the wealth holdings of households around the world for the period since the year 2000. While the Credit Suisse Global Wealth Report highlights the main findings of our study, this 159-page Databook underlines the extent of our analysis. More importantly, it sets out in detail the data employed in our Global Wealth project, the methodology used to calculate estimates of wealth and how this may differ from other reports in this field.

The Credit Suisse Global Wealth Databook also details the evolution of household wealth levels through the period 2000 to mid-2012, providing data at both regional and country level on high net worth individuals, and highlighting the wealth pyramid in addition to wealth analysis for 216 countries. This rich data set has enabled our in-depth study of household indebtedness in Chapter 4 of the Wealth Report. Finally, the Databook presents detailed data on relatively under-researched areas, such as the historical wealth series, inheritance and age effects and the composition of household portfolios (assets and debts).

# 1. Estimating the pattern of global household wealth

## 1.1 Introduction

We aim to provide the best available estimates of the wealth holdings of households around the world for the period since the year 2000. To be more precise, we are interested in the distribution within and across nations of individual net worth, defined as the marketable value of financial assets plus non-financial assets (principally housing and land) less debts. No country in the world has completely reliable information on personal wealth, and for many countries there is little direct evidence. So we are obliged to assemble and process information from a variety of different sources.

The procedure involves three main steps, the first two of which mimic the structure followed by Davies et al (2008, 2011). The first step establishes the average level of wealth for each country. The best source of data for this purpose is household balance sheet (HBS) data which are now provided by 48 countries, although 31 of these countries cover only financial assets and debts. An additional 3 countries have household survey data from which wealth levels can be calculated. Together these countries cover 66% of the global population and 95% of total global wealth. The results are supplemented by econometric techniques which generate estimates of the level of wealth in 150 countries which lack direct information for one or more years.

The second step involves constructing the pattern of wealth holdings within nations. Direct data on the distribution of wealth are available for 20 countries. Inspection of data for these countries suggests a relationship between wealth distribution and income distribution which can be exploited in order to provide a rough estimate of wealth distribution for 143 other countries which have data on income distribution but not on wealth ownership.

It is well recognized that the traditional sources of wealth distribution data are unlikely to provide an accurate picture of wealth ownership in the top-tail of the distribution. To overcome this deficiency, the third step makes use of the information in the "Rich Lists" published by Forbes Magazine and elsewhere to adjust the wealth distribution pattern in the highest wealth ranges.

Implementing these procedures leaves 50 countries for which it is difficult to estimate either the level of household wealth or the distribution of wealth, or both. Usually the countries concerned are small (e.g. Andorra, Bermuda, Guatemala, Monaco) or semi-detached from the global economy (e.g. Afghanistan, Cuba, Myanmar, North Korea), but not in every instance (e.g. Angola, Nigeria). For our estimates of the pattern of global wealth, we assign these countries the average level and distribution of the region and income class to which they belong. This is done in preference to omitting the countries altogether, which would implicitly assume that their pattern of wealth holdings matches the world average. However, checks indicate that excluding these nations from the global picture makes little difference to the results.

Table 2-1 lists the 216 countries in the world along with some summary details. Note that China and India are treated as separate regions due to the size of their populations.

The following sections describe the estimation procedures in more detail. Two other general points should be mentioned at the outset. First, we use official exchange rates throughout to convert currencies to our standard measure of value, which is US dollars at the time in question. In international comparisons of consumption or income it is common to convert currencies using "purchasing power parity" (PPP) exchange rates, which take account of local prices, especially for non-traded services. However, in all countries a large share of personal wealth is owned by

households in the top few percentiles of the distribution, who tend to be internationally mobile and to move their assets across borders with significant frequency. For such people, the prevailing foreign currency rate is most relevant for international comparisons. So there is a stronger case for using official exchange rates in studies of global wealth.

The second issue concerns the appropriate unit of analysis. A case can be made for basing the analysis on households or families. However, personal assets and debts are typically owned (or owed) by named individuals, and may be retained by those individuals if they leave the family. Furthermore, even though some household assets, such as housing, provide communal benefits, it is unusual for household members to have an equal say in the management of assets, or to share equally in the proceeds if the asset is sold. Membership of households can be quite fluid (for example, with respect to older children living away from home) and the pattern of household structure varies markedly across countries. For all these reasons – plus the practical consideration that the number of households is unknown in most countries – we prefer to base our analysis on individuals rather than household or family units. More specifically, since children have little formal or actual wealth ownership, we focus on wealth ownership by adults, defined to be individuals aged 20 or above.

## 1.2 Household balance sheet data

The most reliable source of information on household wealth is household balance sheet (HBS) data. As shown in Table 1-1, “complete” financial and non-financial (“real”) balance sheet data are available for 17 countries for at least one year. These are predominantly high income countries, the exceptions being the Czech Republic and South Africa which fall within the upper middle income category according to the World Bank. The data are described as complete if financial assets, liabilities and non-financial assets are all adequately covered. Another 31 countries have financial balance sheets, but no details of real assets. This group contains 11 upper middle income countries and 6 lower middle income countries, and hence is less biased towards the rich world. The sources of these data are recorded in Table 1-2.

Europe and North America, and OECD countries in particular, are well represented amongst countries with HBS data, but coverage is sparse in Africa, Asia and Latin America. Fortunately survey evidence on wealth is available for the largest developing countries – China, India and Indonesia – which compensates to some extent for this deficiency. Although only financial HBS data are available for Russia, complete HBS data are available for the Czech Republic and financial data are recorded for nine other former socialist countries in Europe.

## 1.3 Household survey data

Information on assets and debts is collected in nationally representative surveys undertaken in an increasing number of countries (see Table 1-3 for the current list and sources.) For three countries this is the only data we have, and we use it to estimate wealth levels as well as distributions. Data on wealth obtained from household surveys vary considerably in quality, due to the sampling and non-sampling problems faced by all sample surveys. The high skewness of wealth distributions makes sampling error important. Non-sampling error is also a problem due to differential response rates – above some level wealthier households are less likely to participate – and under-reporting, especially of financial assets and debts. Both of these problems make it difficult to obtain an accurate picture of the upper tail of the wealth distribution. To compensate, wealthier households are over-sampled in an increasing number of surveys, such as the US Survey of Consumer Finances and similar surveys in Canada, Germany and Spain. Over-sampling at the upper end is not routinely adopted by the developing countries which include asset information in their household surveys, but the response rates are much higher than in developed countries, and the sample sizes are large in China and India: 16,035 for the 2002 survey in China, and 139,039 for the 2002–03 survey in India.

The US Survey of Consumer Finance is sufficiently well designed to capture most household wealth, but this is atypical. In particular, surveys usually yield lower totals for financial assets compared with HBS data. However, surveys do remarkably well for owner-occupied housing, which is the main component of non-financial assets (see Davies and Shorrocks, 2000, p. 630). Our methodology recognizes the general under-reporting of financial assets in surveys and attempts to correct for this deficiency.

Other features of the survey evidence from developing countries capture important real differences. Very high shares of non-financial wealth are found for the two low-income countries in our sample, India and Indonesia, reflecting both the importance of land and agricultural assets and the lack of financial development. On the other hand, the share of non-financial assets in China is relatively modest, in part because urban land is not privately owned. In addition, there has been rapid accumulation of financial assets by Chinese households in recent years. Debts are very low in India and Indonesia, again reflecting poorly developed financial markets.

For countries which have both HBS and survey data, we give priority to the HBS figures. The HBS estimates typically use a country's wealth survey results as one input, but also take account of other sources of information, and should, therefore dominate wealth survey estimates in quality. However, this does not ensure that HBS data are error-free.

## 1.4 Estimating the level and composition of wealth for other countries

For countries lacking direct data on wealth, we use standard econometric techniques to estimate per capita wealth levels from the 51 countries with HBS or survey data in at least one year. Data availability limits the number of countries that can be included in this procedure. However, we are able to employ a theoretically sensible model that yields observed or estimated wealth values for 166 countries, which collectively cover 94% of the world's population in 2012. There is a trade-off here between coverage and reliability. Alternative sets of explanatory variables could achieve greater country coverage, but not without compromising the quality of the regression estimates.

Separate regressions are run for financial assets, non-financial assets and liabilities. Because errors in the three equations are likely to be correlated, the seemingly unrelated regressions (SUR) technique due to Zellner (1962) is applied, but only to financial assets and liabilities, since there are fewer observations for non-financial assets. The independent variables selected are broadly those used in Davies et al (2011). In particular, we include a dummy for cases where the data source is a survey rather than HBS data. This turns out to be negative and highly significant in the financial assets regression, indicating that the average level of financial assets tend to be much lower when the data derive from sample surveys. We use this result to adjust upwards the value of financial assets in the wealth level estimates for Chile, China, India and Indonesia, and also in the distributional calculations for these countries where possible. We also include region-income dummies to capture any common fixed effects at the region-income level, and year dummies to control for shocks – like the recent financial crisis – or time trends that affect the world as a whole.

The resulting estimates of net worth per adult and the three components are reported in Table 2-4 for each year from 2000 to 2012. HBS data are used where available (see Table 1-1); corrected survey data are used for Chile, China, India and Indonesia in specific years. Financial assets and liabilities are estimated for 136 countries, and non-financial assets for 153 countries in at least one year using the regressions described in the previous section.

There remain 50 countries containing 6% of the global adult population without an estimate of wealth per adult. In order to generate wealth figures for regions and for the world as a whole, we assigned to each of these countries the mean wealth per adult of the corresponding region (six categories) and income class (four categories). This imputation is admittedly crude, but

better than simply disregarding the excluded countries, which would implicitly assume (incorrectly) that the countries concerned are representative of their region or the world.

For a few countries, including the USA, wealth levels are available for the most recent years, including the first quarter of 2012. However, the majority of countries are missing wealth levels for at least part of the years 2009, 2010, 2011 and 2012. In order to obtain estimates of net worth per adult and its components we update the most recent available figures using, when available, house price growth for non-financial assets, market capitalization for financial assets and GDP per capita growth for debts (see Table 1-4). For countries without information on house prices and market capitalization, recent growth of GDP per capita is used to project net worth per adult forwards to mid-2012.

## 1.5 Wealth distribution within countries

To analyze the global pattern of wealth holdings by individuals requires information on the distribution of wealth within countries. Direct observations on wealth distribution across households or individuals are available for 20 countries. One set of figures was selected for each of these nations, with a preference for the most recent year, and for the most reliable source of information. Summary details are reported in Table 1-5 using a common template which gives the shares of the top 10%, 5%, 1%, together with other distributional information in the form of cumulated shares of wealth (i.e. Lorenz curve ordinates).

The data differ in various respects. The unit of analysis is usually a household or family, but sometimes an individual (of any age) or an individual adult. More importantly, the data derive from different sources. Household sample surveys are employed in the majority of countries, so in these cases the wealth shares of the top groups are expected to be understated, because wealthy households are less likely to respond, and because the financial assets that are of greater importance to the wealthy – for example, equities and bonds – are especially likely to be under-reported. Other published wealth distribution figures are estimated by government departments from estate tax returns (France) or wealth tax records (Switzerland). These data may be less subject to response bias, but may be more prone to valuation problems, especially in connection with pension assets and debts.

The summary details reported in Table 1-5 show relatively sparse distributional information. Estimates for the empty cells were generated by an “ungrouping” computer program which constructs a synthetic sample which conforms exactly to any set of Lorenz values derived from a positive variable (Shorrocks and Wan 2009).

For most countries lacking direct wealth distribution data, the pattern of wealth distribution was constructed from information on income distribution, based on the belief that wealth inequality is likely to be highly correlated with income inequality across countries. Income distribution data for 143 countries was compiled from the World Development Indicators of the World Bank and the World Income Inequality Database, with priority given to the most recently available year. The “ungrouping” program was then used to generate all the Lorenz curve values required for the template employed for wealth distribution.

This common template allows the wealth and income Lorenz curves to be compared for the 20 reference countries with wealth distribution data. The Lorenz curves for wealth are everywhere lower than for income, indicating that wealth is more unequally distributed than income. Since the ratios of wealth shares to income shares at a given point are roughly similar across countries, we generated estimates of wealth distribution for 143 countries which have income distribution data but no wealth data by applying the average wealth to income ratio for the 20 reference countries to the Lorenz figures for income.

The group of 163 countries with actual or estimated wealth distribution data differs slightly from the group of 166 nations which have figures for mean wealth derived from actual data or the regressions of Section 2. Distributional evidence is more common for populous countries, so the

group of 163 nations now includes Cuba, Iraq, Myanmar, Nepal, Serbia, Sudan, and Uzbekistan, and covers 97.7% of the global adult population.

For the purpose of generating regional and global wealth patterns, to each country lacking income distribution data we assigned a wealth distribution pattern equal to the (adult population weighted) average of the corresponding region and income class. This again was done in preference to simply disregarding the countries concerned.

## 1.6 Assembling the global distribution of wealth

To construct the global distribution of wealth, the level of wealth derived for each country was combined with details of its wealth pattern. Specifically, the ungrouping program was applied to each country to generate a set of synthetic sample values and sample weights consistent with the (actual, estimated or imputed) wealth distribution. Each synthetic sample observation represents 10000 adults in the bottom 90% of the distribution, 1000 adults in the top decile, and 100 adults in the top percentile. The wealth sample values were then scaled up to match the mean wealth of the respective country, and merged into a single world dataset comprising 1.29 million observations.

The complete global sample may be processed in a variety of ways, for example to obtain the minimum wealth and the wealth share of each percentile in the global distribution of wealth. The distribution within regions may also be calculated, along with the number of representatives of each country in any given global wealth percentile.

## 1.7 Adjusting the upper wealth tail

The survey data from which most of our wealth distribution estimates are derived tend to under-represent the wealthiest groups and to entirely omit ultra high net worth individuals. This deficiency does not affect our estimates of average wealth levels around the world, since these are determined by other methods. It does however suggest that unless adjustments are made our figures for the shares of the top percentile and top decile are likely to err on the low side. We would also not expect to generate accurate predictions of the number and value of holdings of high net worth individuals.

We tackle this problem by exploiting well-known statistical regularities in the top wealth tail and by making use of information on the wealth holdings of named individuals revealed in the "rich list" data published by Forbes magazine and elsewhere. As described in more detail in Section 3, the number of billionaires reported by Forbes was used to fit a Pareto distribution to the upper tail of each of the 59 countries listed as having one or more billionaires. The top wealth values in the synthetic sample were then replaced by the new estimates, and the resulting sample for each country was re-scaled to match the mean wealth value. This sequence was repeated until the process converged, typically after a few rounds.

The overall global weighted sample still contains 1.29 million observations, each representing between 100 and 10,000 adults. The adjusted sample can be used to produce improved estimates of the true wealth pattern within countries, regions and the world. The minimum sample size of 100 allows reliable estimates the number and value of wealth holdings up to USD 100 million at the regional and global level. Estimates above this level (as well as for individual countries) can be obtained from forward projections based on a Pareto distribution.

## 1.8 Concluding remarks

The study of global household wealth is at an embryonic stage. Data on the level of wealth remains poor for many countries. Information on the pattern of wealth within countries is even scarcer. The precise definition of personal wealth has not been agreed, and the appropriate methods of valuation are not always clear. Much work remains to be done to refine the estimates of wealth level by country, to improve the estimates of wealth distribution within countries, to explore the pattern of wealth holdings within families, and so on. In future years, some revisions to our estimates are inevitable, and some country rankings will no doubt change. But we are confident that the broad trends revealed in the Credit Suisse Global Wealth Report for 2012 will remain substantially intact.

## 2. An overview of household wealth levels, 2000–2012

### 2.1 Introduction

As explained in Section 1, our ambition is to generate the global pattern of household wealth. The first stage in this process is to provide an estimate of the average level of household wealth and its core components for every country and every year since 2000.

Table 2-1 identifies 216 countries in 2012 and reports some core variables, including the classification by region, by income class according to the World Bank, and our assessment of the quality of wealth data.

Population figures are available for all countries and years and are reported in Table 2-2. Figures for the number of adults, i.e. individuals aged 20 or above, are also available for most countries and years. Where the data are not reported elsewhere, we estimate the number of adults by assuming that the adult ratio is the (population weighted) average for the corresponding region and income class. The results are summarized in Table 2-3.

The procedure outlined in Section 1 describes the three ways in which wealth levels data are assembled: direct estimates via national household balance sheets (HBS) or household surveys; regression estimates using likely correlated variables; and imputations based on the region-income class average. In practice the situation is slightly more complicated because some countries have direct observations for, say, financial wealth, but require non-financial wealth to be estimated. In addition, very few countries have direct estimates beyond 2008 and many countries lack data on the core regressors in recent years. Almost all figures for 2009, 2010, 2011 and 2012 are therefore obtained by updating the estimate for the most recent year using subsequent movements in stock market indices, house price indices, or – if nothing better is available – growth of GDP.

In Table 2-1, we do our best to summarize the quality of wealth data for each country on a five-point scale. A country gets five points, and a “good” rating if it has complete HBS data, and either wealth distribution data or a good basis for estimating the shape of the wealth distribution. A “satisfactory” rating and four points go to countries that would get a “good” rating except that their HBS data does not cover non-financial assets. These countries must have a full set of independent variables allowing regression-based estimates of non-financial assets. Countries without any HBS data but with a household wealth survey or other wealth distribution data (from estate tax or wealth tax sources) get a “fair” rating and three points. A poor rating (two points) goes to countries without HBS or wealth distribution data, but having a full set of independent variables allowing estimation of their wealth levels. If some independent variables are missing but the regressions can still be performed, the rating is “very poor” (one point).

In Table 2-1, there are 50 countries for which wealth data quality is not assessed. These are the countries for which we have no sensible basis for estimating wealth. In calculating the regional and global wealth figures, we assign these countries the region-income class average; but the separate country data are not reported in the later tables. This leaves the remaining 166 countries, 5 regions (other than China and India), and 1 global category listed in Table 2-4 for each of the 13 years from 2000 to 2012. Most of the column content is self explanatory. The last column indicates the estimation method used for the wealth levels, grouped into five categories. Most figures up to 2008 are labeled as either (1) “HBS”, indicating data from official household balance sheets, (2) “survey data”, or (3) “regression”, referring to estimated values based on wealth regressions. When multiple methods are employed (e.g. for financial assets and non-financial assets), we report either “HBS” or “survey data” as appropriate. Two labels

are typically reported for recent years. “Updated HBS” and “Updated regression” mean HBS data (respectively, regression estimates) updated using market capitalization growth for financial assets, house prices for non-financial assets and GDP per capita growth for debts; For countries lacking information on house prices or market capitalization, GDP per capita growth was used to project net worth per adult forward to the years 2009, 2010, 2011 and 2012.

**Figure 2-1: Aggregate global wealth, 2000–12**

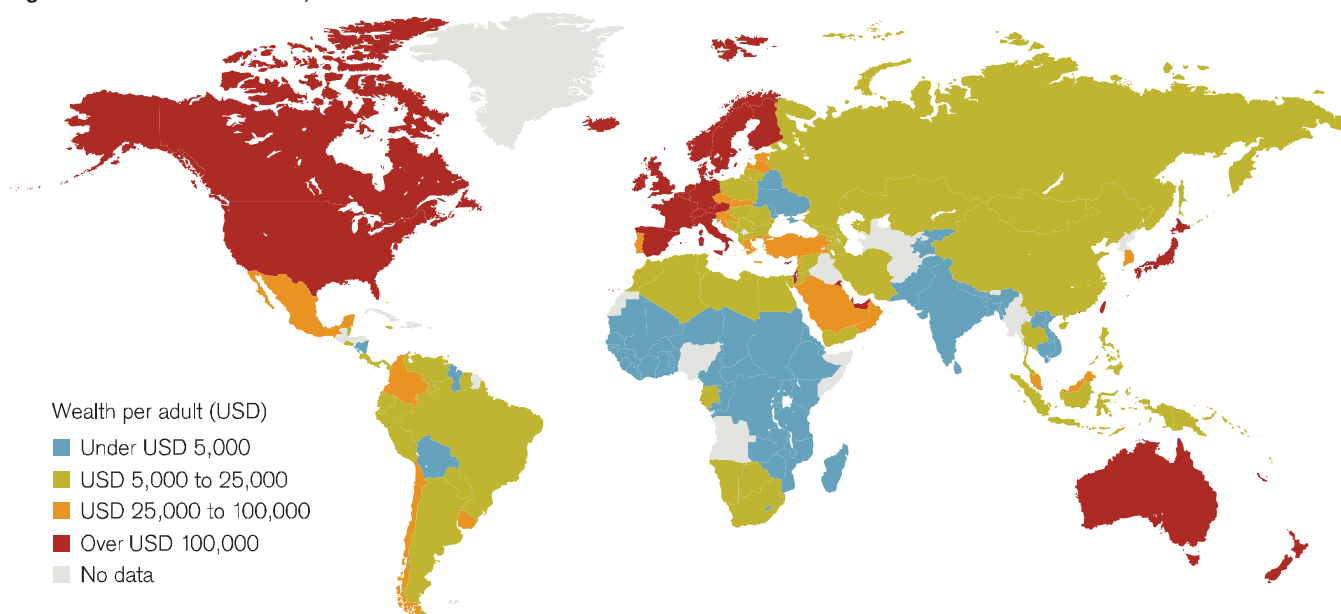

## 2.2 Trends in household wealth 2000–12

Our figures show that global household wealth totaled USD 222.7 trillion in mid-2012, equivalent to USD 48,500 for each of the 4.6 billion adults in the world. The corresponding values for the end of the year 2000 are USD 113.4 trillion in aggregate and an average of USD 30,700 for the 3.6 billion adults alive at that time. Thus global household wealth rose by 96% between end-2000 and mid-2012 and wealth per adult climbed 58%. Figure 2-1 displays the trend in aggregate household wealth over the intervening years, showing vividly the drop in household wealth between 2007 and 2008 caused by the global financial crisis, and the subsequent recovery to a level in 2011 similar to the 2007 peak. Despite the 2007–08 crisis, it appears that the past decade has been a relatively benign period for household wealth accumulation. However, the overall picture is distorted slightly by valuing wealth in terms of US dollars. Over the period under analysis, the US dollar depreciated against most major currencies, accounting for part of the rise in dollar-denominated values. Holding exchange rates constant, the rise in average net worth over the decade is a more modest 37% (see Table 2-5).

The regional distribution of aggregate personal wealth is also captured in Figure 2-1. During the past year, economic uncertainty and exchange rate movements have reduced dollar denominated wealth everywhere apart from North America and China. The decline has been sufficient to return India and Europe below the 2007 peak. While Europe remains the region with the highest total wealth, the excess over North America is now just USD 1.2 trillion, the smallest gap since Europe overtook North America in 2006. Europe now accounts for 31.1% of global wealth, Northern America 30.6% and Asia-Pacific (excluding China and India) for 22.8%. The rest of world owns the remaining 15% of total household wealth, although it contains 60% of the global adult population.

Figure 2-2: World wealth levels, mid-2012

### 2.3 Variations across countries

The figure for average global wealth masks considerable variation across countries and regions (see Figure 2-2). The richest nations, with wealth per adult over USD 100,000, are found in North America, Western Europe, and among the rich Asia-Pacific and Middle East countries. They are headed by Switzerland, which in 2011 became the first country in which average wealth exceeded USD 500,000. Exchange rate changes have reduced its wealth per adult from USD 540,000 in 2011 to USD 470,000 in 2012; but this still remains considerably higher than the level in Australia (USD 350,000) and Norway (USD 330,000), which retain second and third places despite falls of about 10%. Close behind are a group of nations with average wealth above USD 200,000, many of which have experienced double digit depreciation against the US dollar, such as France, Sweden, Belgium, Denmark and Italy. Those countries in the group which have not been adversely affected have moved up the rankings – most notably Japan to fourth place with wealth of USD 270,000 per adult and the United States to seventh place with USD 260,000 per adult.

In terms of wealth per adult, the set of richest countries has been very stable. During the past year only Greece has dipped below the USD 100,000 threshold, although Spain and Cyprus are close to demotion with average wealth of USD 105,000 and USD 113,000, respectively. Greece joins other EU countries (Portugal, Malta, Slovenia) at the top of the “Emerging Wealth” group with mean wealth in the range from USD 25,000 to USD 100,000. Recent EU entrants (Czech Republic, Estonia, Slovakia) are found lower down this band, but several others (Hungary, Poland, Lithuania, Romania) have been demoted during the past year. The Emerging Wealth band also encompasses a number of Middle Eastern nations (Oman, Bahrain, Lebanon, Saudi Arabia) and several Latin American countries (Chile, Mexico, Uruguay, Costa Rica). Columbia has been promoted to the group, but Brazil has moved in the opposite direction, together with its BRICS colleague South Africa.

The “Frontier Wealth” range from USD 5,000 to 25,000 per adult covers the largest number of countries and most of the heavily populated ones including China, Russia, Indonesia, Brazil, Pakistan, Philippines, Turkey, Egypt and Iran. The band also contains many transition nations outside the EU (Albania, Armenia, Azerbaijan, Bosnia, Georgia, Serbia, Kazakhstan and Mongolia), most of Latin America (Argentina, Ecuador, El Salvador, Panama, Paraguay, Peru, Venezuela), and many countries bordering the Mediterranean (Algeria, Jordan, Libya, Morocco,

Syria and Tunisia). South Africa is now alongside other leading sub-Saharan nations in this group: Botswana, Equatorial Guinea, Namibia, and Swaziland.

The final category with wealth below USD 5,000 remains heavily concentrated in Africa, although the overall geographical composition shifted this year when India dropped down to join other major Asian nations (Bangladesh, Cambodia, Laos, Nepal, Sri Lanka, Viet Nam). Belarus, Moldova and Ukraine are three countries bordering the EU which also languish in the middle of this wealth range.

**Figure 2-3: Global trends in wealth per adult and its components**

Source: Original estimates; see text for explanation of methods

## 2.4 Composition of household portfolios

Table 2-4 records values for three core subcomponents of household wealth: financial assets, non-financial assets (principally housing and land), and debts. These components of wealth portfolios are interesting in their own right, and vary widely and systematically across countries. Average household net worth was on an upward trend from 2000 until the crisis in 2007, then fell by approximately 10% before recovering in 2011 to slightly above the pre-crisis level. The further setbacks this year have pushed wealth per adult back below the earlier peak. However, as Figure 2.3 shows (see also Table 2-5), exchange rate movements account for much of the year-on-year variation. Using constant USD exchange rates yields a smoother time trend, and a single significant downturn in 2008, after which the recovery has continued more or less unabated.

The time series for the financial and nonfinancial components of wealth have closely followed the pattern for net worth, and both have now returned below the 2007 peak. At the start of the millennium, financial assets accounted for well over half of the household portfolio, but the share declined up to 2008, at which point the global wealth portfolio was equally split between financial and non-financial assets (mostly property). In the period since 2008, the balance has again tipped slightly towards financial assets.

On the liability side of the household balance sheet, average debt rose by 80% between 2000 and 2007, and then leveled out. It now amounts to USD 8600 per adult, about 7% less than the same time a year ago. Expressed as a proportion of household assets, average debt has moved in a narrow range, rising over the period, but never exploding.

The composition of household portfolios varies widely and systematically across countries. The most persistent feature is the rise in the relative importance of both financial assets and liabilities with the level of development. For instance, financial assets are 43.1% of gross assets in Europe and 67.1% in North America, but just 15.9% of gross assets in India. Household debt as a percent of gross assets is 16% in Europe and 18.1% in North America, but only 3.7% in India and 8.7% in Africa. There is also variation in portfolios unrelated to level of development. Some developed countries, like Italy, have unusually low liabilities (10.0% of gross assets) while others have surprisingly high debt, like Denmark (33.7% of gross assets). In addition, the mix of financial assets varies greatly, reflecting national differences in financial structure. The share of equities in total financial assets, for example, ranges from 43.4% in the USA, down to just 20.1% and 6.5% in Germany and Japan respectively. We return to this issue in Section 6 of the Databook, where international variations in household portfolios are examined in more detail.

## 3. Estimating the distribution of global wealth

### 3.1 Comparison with data from “rich lists”

Our method of estimating global personal wealth is essentially a “bottom-up” approach. It begins by establishing the average level of wealth in different countries onto which we graft the pattern of wealth holding revealed in household sample surveys and other sources. Although sample surveys do not formally exclude high net worth (HNW) individuals with net assets above USD 1 million, they are not always captured, and the value of their wealth holdings is likely to be underestimated. The same is true to a much greater extent for ultra high net worth (UHNW) individuals with net assets above USD 50 million. In fact, the US Survey of Consumer Finances, which otherwise does an excellent job in the upper tail of the wealth distribution, explicitly omits the 400 wealthiest families from its sampling frame. This is not enough to completely invalidate our general approach: for example, the world’s billionaires reported by Forbes magazine for the year 2012 were collectively worth about USD 4.6 trillion, which equates to 2% of our estimate of USD 223 trillion for total world household wealth. However, further analysis and appropriate adjustments are required in order to paint an accurate picture of the number of the wealthiest individuals and the size of their holdings.

In order to proceed, we exploit the fact that the top tail of wealth distributions is usually well approximated by the Pareto distribution which produces a straight line graph when the logarithm of the number of persons above wealth level  $w$  is plotted against the logarithm of  $w$ . Our data yield a close fit to the Pareto distribution in the wealth range from USD 250,000 to USD 5 million. Above USD 5 million the relationship begins to break down, and the correspondence weakens further above USD 50 million, as expected given the limitations of the data sources and the lumpiness caused when each sample observation represents at least 100 adults. However, it seems reasonable to use a fitted Pareto line to estimate the number of individuals in the highest echelons of the wealth distribution.

The true beneficial ownership within families adds a further level of complexity. Assigning the wealth recorded for Bill Gates, for example, to all family members might well result in several (unequal) billionaire holdings, so the number of billionaires would increase in this instance. In other cases, reassigning the family wealth would reduce all the individual holdings below the billionaire threshold.

The “rich lists” provided by Forbes and other sources have other limitations for our purposes. The figures are dominated by financial assets, especially equity holdings in public companies traded in international markets. For practical reasons, less attention is given to non financial assets apart from major real estate holdings and trophy assets, such as expensive yachts; and even less is known – and hence recorded – about personal debts. Some people cooperate enthusiastically with those compiling the lists; others prefer to protect their privacy. There are also different country listings for nationals and residents, which is especially evident for India, for instance. As a consequence, the rich list data should be treated with caution. At the same time, the broad patterns and trends are informative, and they provide the best available source of information at the apex of the global wealth distribution.

### 3.2 Adjusting the wealth pattern in the top tail

For each of the 59 countries listed by Forbes magazine as having one or more billionaires in 2012, we grafted a Pareto distribution onto the upper tail which matched the reported number of billionaires, and then replaced the synthetic sample observations in the top tail with the fitted Pareto values. To add a further level of refinement, the number of Forbes billionaires – which

Figure 3-1: Unadjusted and adjusted wealth values for China, 2012

Source: Original estimates; see text for explanation of methods

we assume refer to billionaire families – is converted into the equivalent number of high wealth adults. When the top wealth values have been revised, all the sample observations for a country are scaled up or (more usually) down in order to restore consistency with the average level of wealth for the country, which is estimated independently. This was repeated until the process converges, typically in a few rounds.

For countries with satisfactory wealth distribution data, the adjustment has little impact on wealth holdings below USD 1 million. However, the required adjustment is more extensive for countries for which wealth distribution data is limited or non-existent. The impact on China is especially noticeable, not surprisingly given that the wealth distribution data for China are based on a sample survey a decade ago and given the pace of change since then. Figure 3-1 portrays the original wealth distribution for China and the final adjusted pattern consistent with the 80 billionaires reported in 2012.

### 3.3 Features of the global wealth distribution

The revised synthetic sample still contains 1.29 million observations, each representing between 100 and 10,000 adults, which may be processed to generate improved estimates of the wealth pattern within countries, regions and the world. Table 3-1 summarizes results for individual countries, and Table 3-2 provides more detail at the regional level. The wealth pyramid (Figure 3-2) vividly captures the essential features of the global wealth distribution divided into four segments: under USD 10,000; between USD 10,000 and USD 100,000; between USD 100,000 and USD 1 million; and over USD 1 million.

Combining the samples for all countries allows the overall features of the global distribution of wealth to be identified, including, for instance, the minimum wealth of each percentile (i.e. 1% group) and the share of total wealth owned by this group. To be among the wealthiest half of the world, an adult needs only USD 3,700 in assets, once debts have been subtracted.

However, a person needs at least USD 71,000 to belong to the top 10% of global wealth holders and USD 710,000 to be a member of the top 1%. The bottom half of the global population together possess barely 1% of global wealth, although wealth is growing fast for some members of this segment. In sharp contrast, the richest 10% own 86% of the world’s wealth, with the top 1% alone accounting for 46% of global assets. Table 3-3 reports the

Figure 3-2: The global wealth pyramid

Source: Original estimates; see text for explanation of methods

regional and country level distribution within each of the global deciles (i.e. 10% groups), and Figure 3-3 portrays the regional pattern graphically. For adults with wealth exceeding USD 100,000 and USD 1 million, Table 3-4 provides details of the number of members for countries with the greatest representation.

The comparison between China and India is a core feature of Figure 3-3. China has very few representatives at the bottom of the global wealth distribution and relatively few at the top, but dominates the upper middle section, hosting 40% of those in deciles 6-9. The sizeable presence of China in this section reflects not only its population size and its growing average wealth, but also wealth inequality which, despite recent increases, remains modest by the standards of the developing world. China's position in the global picture has shifted towards the right in the past decade due to its strong record of growth, rising asset values, and currency appreciation. China now has more people in the top 10% of global wealth holders than any country except for the USA and Japan, having moved into third place in the ranking by overtaking Italy and Germany. In contrast, residents of India are heavily concentrated in the lower wealth strata, accounting for a quarter of people in the bottom half of the distribution. However, its extreme wealth inequality and immense population means that India also has a significant number of members in the top wealth echelons.

As Figure 3-3 shows, residents of Asia-Pacific nations (excluding China and India) are fairly evenly spread across the global wealth spectrum. However, this uniformity masks a substantial degree of polarization. Members of high-income Asian countries, such as Japan, Singapore and Hong Kong, are heavily concentrated at the top end: half of all adults in high income Asian countries are placed in the top global wealth decile. In contrast, residents of lower income countries in Asia, such as Indonesia, Bangladesh, Pakistan and Viet Nam, tend to be found much lower down in the wealth distribution. In fact, when high income countries are excluded from the Asia-Pacific group, the wealth pattern within the remaining countries resembles that of India, with both regional groupings contributing about one quarter of the bottom half of wealth holders. Africa is even more concentrated at the bottom end. Half of all African adults are found in the bottom two global wealth deciles. At the same time, wealth inequality within and across countries in Africa is so high that some individuals are found among the top 10% of global wealth holders, and even among the top 1%.

Latin America is another region whose wealth distribution closely mimics the global pattern, with individuals fairly evenly spread across the wealth deciles. North America and Europe are much more skewed towards the high end, together accounting for 60% of those in the top 10%, and an even higher fraction of the top percentile. Europe alone is home to 36% of members of the top wealth decile, a proportion that rose considerably during the past decade as the euro appreciated against the US dollar, but has declined a little during the past 12 months.

Figure 3-3: Regional composition of global wealth distribution, 2012

### 3.4 The number of high and ultra high net worth individuals

Apart from the rich lists, which cover a relatively small number of named individuals, there is a scarcity of information on wealth holdings above USD 1 million. Survey details are patchy at best, and official statistics based on tax returns are often inadequate given the complexity of wealth ownership arrangements. We bridge this gap by using a Pareto curve fitted to the data for each country to smooth the wealth distribution among the HNWI and UHNWI groups, so that the pattern of wealth holdings above USD 1 million can be determined with more confidence.

Table 3-5 reports the numbers for mid-2012. While the base of the wealth pyramid is occupied by people from all countries of the world at various stages of their lifecycles, HNWI and UHNWI individuals are heavily concentrated in particular regions and countries, and tend to share a similar lifestyle, participating in the same global markets for high coupon consumption items even when located on different continents. The wealth portfolios of individuals are also likely to be similar, dominated by financial assets and, in particular, equity holdings in public companies traded in international markets. For these reasons, using official exchange rates to value assets is more appropriate than using local price levels.

We estimate that 28.5 million HNWI individuals had wealth from USD 1 million to USD 50 million in mid 2012, of whom the vast majority (25.6 million) fall in the USD 1–5 million range. A year ago, Europe overtook North America as the region with the greatest number of HNWI individuals, but tradition has been restored this year, with 11.8 million residents (42% of the total) in North America, and 9.2 million (32%) in Europe. Asia-Pacific countries excluding China and India are home to 5.7 million members (20%), and we estimate that there are currently a fraction under 1 million HNWI individuals in China (3.4% of the global total). The remaining 753,000 HNWI individuals (2.6% of the total) reside in India, Africa or Latin America.

Our estimates suggest that there are 84,500 UHNWI individuals worldwide with net assets exceeding USD 50 million. Of these, 29,300 are worth at least USD 100 million and 2,700 have assets above USD 500 million. North America dominates the regional ranking, with 40,000 UHNWI residents (47%), while Europe hosts 22,000 individuals (26%), and 12,800 (15%) reside in Asia-Pacific countries, excluding China and India.

In terms of single countries, the USA leads by a huge margin with 37,950 UHNWI individuals, equivalent to 45% of the group. The recent fortunes created in China have propelled it into

second place with 4,700 representatives (5.6% of the global total), followed by Germany (4,000), Japan (3,400), United Kingdom (3,200) and Switzerland (3,050). Numbers in other BRIC countries are also rising fast, with 1,950 members in Russia, 1,550 in India and 1,500 in Brazil. Among emerging markets, strong showings are evident in Taiwan (1,200), Hong Kong (1,100) and Turkey (1,000).

### 3.5 Changing membership of the top wealth groups

The changes observed in wealth per adult have also affected the pattern of wealth distribution. The overall decline in USD denominated average wealth has raised the proportion of adults with wealth below USD 10,000, from 67.6% in mid 2011 to 69.3% in mid 2012, and reduced the number of millionaires by slightly more than a million (see Table 3-6). There were 962,000 new millionaires in the United States and 460,000 in Japan, but no significant increase in numbers elsewhere. However, Europe shed almost 1.8 million dollar millionaires, most notably in Italy (-374,000), France (-322,000), Germany (-290,000), Denmark (-179,000), Sweden (-142,000) and Spain (-87,000). Australia, Canada, Brazil and Taiwan were the other countries among the top ten losers. The losses in were sufficient to drop Brazil, Denmark and Taiwan (along with Belgium) from the list of countries hosting more than 1% of the total number of millionaires worldwide.

Rather perversely, we estimate that changes to the shape of the wealth distribution in the United States, Denmark and Canada *reduced* the number of US members in the top global wealth decile (i.e. top 10% of adults) by about 100,000, and increased the number of members residing in Denmark (by over 500,000) and Canada (by 300,000). The apparent contradiction with changes in the number of millionaires is explicable by the fact that membership of the top global wealth decile requires only about USD 71,000 in net assets. We estimate that over six million residents in both Japan and China joined the top global decile along with around half a million new members each in Chile, Colombia and Hong Kong. They displaced about 6 million members of the top decile previously resident in Germany, Italy or Spain, and nearly 5 million adults resident in major developing economies: Brazil, South Africa, India, Mexico and Taiwan.

To belong to the top percentile (i.e. top 1%) of the global wealth distribution requires USD 710,000 in mid 2012, so the group is expected to have a similar composition to that of millionaires, but around twice the number of members (which are relatively fixed in total over time). Our results indicate that almost 4 million US residents moved into the top global wealth percentile along with nearly a million Japanese. As expected, they replaced many residents of eurozone countries: Italy (-705,000), Germany (-509,000), France (-442,000), Belgium (-173,000) and Spain (-154,000). Australia, Denmark, Canada, Brazil and Taiwan shed about another million members between them.

Table: 3-1: Wealth pattern within countries, 2012

## 4. Household debt

### 4.1 Global trends in household debt

Rising household debt has been one of the most enduring and widespread economic trends of the past 30 years. Evidence for G7 countries presented in Table 4-2 suggests that this phenomenon began around 1975. Before this date, the ratio of household debt to annual disposable income within countries remained fairly stable over time and rarely rose above 75%. By the year 2000, household debt in Canada, Germany, the UK and the USA was equivalent to at least 12 months' income, and in Japan it equated to 15 months' income. Household debt in France and Italy started from a much lower base, but the gap narrowed considerably between 1980 and 2000, with the debt to income ratio approximately doubling in France and rising even faster in Italy.

In most G7 countries, these trends continued until the financial crisis, and then moderated or reversed. When the debt to income ratio peaked, it was two times higher than the level in the early 1980s in Canada, France and the USA, it was three times higher than the earlier level in the UK, and ten times higher in Italy. In contrast, the debt-income ratio in Japan has been fairly flat since 1990 and around 2000, it even began to decline slightly in Germany and Japan. While the financial crisis prompted major debt reductions in the UK and the USA after 2007, the trend towards greater indebtedness has carried on regardless in Canada and Italy. Given its history and reputation for prudent economic policies, it is worth noting that Canada currently has the highest household debt-income ratio among G7 countries.

Estimates of household debt are available for all countries since the year 2000. Our calculations suggest that the recent experience of G7 countries was widely replicated elsewhere. Adjusted for exchange rate fluctuations, Table 4-3 shows that total global household debt grew by 8% per annum in 2000–07, and then flattened out. For the entire period 2000–12, aggregate debt rose by 81%, equivalent to 5% growth per annum. A rising global population accounts for part of the increase: debt per adult grew just 45% for the entire period. Currency appreciation against the US dollar has tended to operate in the opposite direction. At prevailing exchange rates, total household debt more than doubled before the financial crisis, rising from USD 18.8 trillion in 2000 to 38.8 trillion in 2007, before flattening out. The current level is USD 39.4 trillion.

### 4.2 Regional patterns of household debt

Table 4-3 indicates that the regional composition of household debt is dominated by North America, Europe and Asia-Pacific countries (excluding China and India), which together account for 94% of the global total. Latin America and Africa, along with China and India, have low levels of aggregate debt and rank even lower in terms of debt per adult. For example, in 2012, the average figure is USD 427 for Africa and USD 162 for India compared to USD 57,063 for North America. However, the pattern is slowly changing. Based on constant exchange rates, debt per adult grew by 150% in China and Africa between 2000 and 2012, by 200% in Latin America, and by almost 250% in India, compared to 45% for the world as a whole and just 7% for the Asia-Pacific region.

### 4.3 Household debt per adult in developed countries

Average debt per adult shows even greater variation across countries than average income or average wealth. The highest levels of debt per adult are found in developed countries with well functioning institutions and sophisticated credit markets. Based on average USD exchange rates since 2000, Denmark, Norway and Switzerland top the league table for household debt per adult in 2012, with values above USD 100,000 (Table 4-4). This is roughly twice the level seen in Canada, Sweden, the USA, the UK and Singapore, with Ireland and the Netherlands sitting between the two groups. By these standards, the average debt per adult in Spain (USD 31,200), Portugal (USD 25,800), Italy (USD 23,900) and Greece (USD 19,000) looks quite modest.

Table 4-4 shows that average debt per adult increased during 2000–07 in all the high debt countries apart from Germany, where average debt has been flat, and Japan, where household debt has declined – possibly due in part to the ageing population, given the negative relationship between debt and age. Countries with the highest debt per adult showed little tendency towards debt reduction in the aftermath of the financial crisis: Ireland, the USA and Hong Kong are the main exceptions. Apart from Germany and Japan, only Hong Kong and Singapore have debt levels in 2012 which are close to the levels recorded at the start of the millennium.

### 4.4 Debt in proportion to wealth

Expressed as a fraction of net worth, household debt is typically 20%–30% of wealth in advanced economies, but much higher levels are sometimes recorded, for example in Ireland (44%), the Netherlands (45%) and Denmark (51%). The reasons lie with both the numerator and the denominator in the ratio of debt to assets. Countries that have a strong welfare state with generous public pensions provide less of a stimulus for households to accumulate financial assets. Public housing has a similar effect on the non-financial side, although its share of the total housing stock has been declining in most countries in recent decades, which makes this argument less compelling. Nevertheless, in Scandinavia and elsewhere, these forces make the debt to assets ratio higher by depressing the denominator. Sophisticated financial institutions and easy access to credit are further reasons why debt is sometimes high. The impact of government policies can also be seen, for instance in high levels of student debt accompanied by a relaxed schedule for student debt repayment. Taking all of these factors into consideration, it is not so surprising that debt can amount to one-third of gross assets – and hence one half of net assets – in a country like Denmark.

The burden attached to the rise in household debt needs to be evaluated in the context of the substantial increase in personal wealth during the past decade. Despite the rise in wealth, in most countries where household debt exceeds USD 1 trillion, the ratio of debt to net worth rose on average by about 50% during the period 2000–08. Debt in the USA increased from 18.7% of net worth in 2000 to peak at 30.5% in 2008 before falling back to 21.7% in 2011. The UK exhibited a very similar pattern, with the debt ratio climbing from 15.2% to 23.4% between 2000 and 2008, subsequently dropping to 20% in 2012. The rise in the debt-wealth ratio was even more precipitous in the Netherlands and Spain, and although the increase abated slightly to 71% in the Netherlands, no reduction is evident in Spain, whose ratio is now 90% higher than it was in 2000.

Debt growth was also high in Italy, but started from a much lower base, with the result that the debt-wealth ratio of 11.1% in 2012 is not just the lowest for a developed nation in Table 4-4, but also below the average for the world as a whole, which is 17.7%. France (12.8%),

Germany (16.4%) and Japan (16.6%) have now also fallen below the global average, with wealth in France growing robustly enough to reduce the debt ratio by about 10% during the past decade, and Germany managing to reduce the ratio by one-third, from 24.3% in 2000 to 16.4% in 2012. Singapore almost matched Germany's performance in reducing the debt burden. Our estimates indicate that Malaysia and the Philippines may have done even better, although the data for these countries are less reliable.

#### 4.5 Household debt in developing and transition countries

Because personal debt is often a sensitive issue, collecting data on debt poses special difficulties for household surveys. This, together with the greater prevalence of informal debt, may help explain why measured household debt is typically low in developing countries – less than 10% of net assets overall. But immature financial markets (and weak property rights) also mean that household demand for credit is often not satisfied. In addition, demand for credit may be constrained by the fact that even small amounts of debt can be a considerable burden for the very poor in developing countries, especially when usurious interest rates are charged.

In the developing world, the absolute level of debt is seldom more than USD 1,000 per adult, but exceptionally high levels – above USD 5,000 per adult – are evident in Brazil, Chile and South Africa (see Table 4-4). Similar levels of household debt are also associated with transition countries that have entered the European Union (EU), such as the Czech Republic, Hungary, Poland, Romania and Slovakia, as well as some that have not, such as Ukraine. At the bottom of the range, we estimate average debt to be below USD 300 in Indonesia, and around USD 200 in India and Vietnam. China (about USD 600) and Russia (about USD 1,300) are examples of intermediate countries.

Low absolute levels of debt make it sometimes appear that developing countries have escaped the trend towards rising household debt in recent years. Exactly the opposite is true. According to the estimates we report in Table 4-5, Malaysia and the Philippines are the only two developing countries for which debt per adult is likely to have grown less than the global average of 45% during 2000–12. Debt per adult more than doubled in Argentina, the Czech Republic, Mexico, Morocco and Uruguay, and more than trebled in Chile, Colombia, India and South Africa. In Indonesia and Slovakia, average debt rose by a factor of five, and in Hungary, Poland, Turkey and Vietnam by a factor of eight. But the biggest changes were recorded in other transition countries: Russia, where average debt increased by a factor of 20 between 2000 and 2007; and Romania and Ukraine, where average debt has seen a fiftyfold increase since 2000.

#### 4.6 Are household debt levels sustainable?

The fact that the wealthiest and most economically successful countries tend to have relatively high levels of household debt suggests that debt is both a blessing and a curse. The problem is understanding how much household debt is needed to oil the wheels of economic progress without precipitating the crises of confidence seen recently in several European nations. Table 4-1 attempts to cast some light on this issue based on the cross-classification of countries according to their debt-wealth ratio and growth in debt per adult.

Several patterns are evident. First, high-income economies congregate in the upper left section of the table: in other words, they tend to have medium or high levels of household debt relative to assets, and low to medium debt growth in recent years. The Nordic region is firmly located within the high debt-medium debt growth category, and the Asian Tigers are typically located in

		Growth in debt per adult, 2000–2012					
		< 5% pa	5%–10% pa		> 10% pa		
Debt-wealth ratio 2012	High > 20%	Hong Kong	Australia	Netherlands	Brazil	Poland

				Iran			

Source: Original estimates; see text for explanation of methods

the medium debt-low debt growth section, with Korea an outlier in this respect. The four upper left cells contain all of the G7 countries but, interestingly, no nation from Latin America.

A second feature is the high growth in debt witnessed in most transition countries in recent years. This is not surprising given the lack of investment opportunities and credit and mortgage facilities in the pre-reform era. What is perhaps unexpected is the speed at which Hungary, Poland, Slovakia and Ukraine have joined the group of countries for which household debt exceeds 20% of net worth. Many Eastern European countries experienced a debt-financed housing boom in the post-reform era, which, when it went into reverse, meant that lower levels of property assets were supporting high levels of mortgage debt. Also, in the high debt ratio-high debt growth category are two of the emerging market leaders – Brazil and South Africa – with Russia close by.

The cross-classification in Table 4-1 is too simplistic to provide a solid basis for policy lessons. Nevertheless, a high ratio of debt to net worth is not itself a negative signal for a country. Indeed, it is close to being a prerequisite for economic success. What is problematic is the speedy growth in household debt. It is worth noting that Greece, Hungary and the United Arab Emirates all appear in the upper right-hand section and all have made headlines in recent years with regard to debt problems. While these headline issues have not been directly linked to household borrowing, the high speed at which household debt has grown is perhaps indicative of a relaxed credit culture that can have further repercussions.

## 4.7 The household burden of government debt

The recent concern over debt sustainability has focused almost exclusively on sovereign debt and the vulnerability of the banking sector. Yet the degree to which governments can finance external debt in times of difficulty depends in part on the net assets of the household sector. More importantly, when considering whether their assets are sufficient to meet future consumption needs and emergencies, households should take account of the debt that governments are accumulating on their behalf.

We have assembled data on government financial assets and debt for the period 2000-11 for 26 countries: Australia, Austria, Belgium, Bulgaria, Canada, Cyprus, the Czech Republic,

Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Japan, Lithuania, the Netherlands, Norway, Poland, Portugal, Romania, Spain, Sweden, the United Kingdom and the United States. Although these data exclude off-balance sheet items such as non-funded state pensions, they nevertheless provide some indication of the net liabilities of governments, how these compare with household net worth, and how the position has changed over time, particularly after the financial crisis.

The overall situation is summarized in Table 4-6. In almost all countries, government liabilities exceeded government financial assets in 2011, leaving the government a net debtor. However, the governments of Bulgaria, Finland and Sweden are all net creditors, and Norway's stabilization fund gives it a huge surplus, amounting to USD 199,000 per adult in 2011, equivalent to 15 times the net financial assets of households. The fact that Nordic countries have a high level of household debt is one of the reasons why government debt tends to be negatively correlated with household debt. Denmark, for example, has the highest household debt to wealth ratio in the world, yet net government debt amounts to just 3% of the net financial wealth of households. In contrast, Japan has moderate household debt, but this is offset by net government debt of USD 77,000 per adult, the highest of any country in our sample.

The negative relationship between government debt and household debt (shown in Figure 4.1) is consistent with so-called Ricardian equivalence, much discussed since 1974 when Barro revived an idea first aired by Ricardo in 1820 (see Barro, 1974; 1979; and Ricardo, 1888). Ricardian Equivalence claims that forward-looking taxpayers will understand that an increase government debt must be paid for in the future through higher taxes. They will therefore save more or reduce their debts when government debt increases. In theory, under idealized conditions (including perfect foresight and a perfect capital market), each dollar rise in government debt would stimulate a dollar increase in household net worth.

As documented by Elmendorf and Mankiw (1999), Ricardian Equivalence has been subjected to extensive empirical testing. While these tests have been inconclusive overall, they have not highlighted the relationship between government debt and household debt across countries. Our finding of a significant negative relationship may well prompt further examination of the relationship between government debt and household liabilities based on international data.

Figure 4.1: Household and government debt as a percentage of financial assets 2011

Source: Original estimates; see text for explanation of methods

## 4.8 Changes over time

Excluding the Nordic region, government net debt averaged 41% of household net financial assets in 2011. Countries with worse-than-average positions are Italy (49%), Japan (56%), Spain (56%), Poland (57%), Hungary (71%), Ireland (92%) and Greece (112%). With the exception of the Nordic countries (Norway, Finland, Denmark and Sweden), Table 4-7 shows that the government's financial position worsened relative to household assets in all countries between 2000 and 2011, particularly after the 2008 financial crisis. Bulgaria, the Czech Republic, Lithuania and Romania all moved from a government surplus in 2000 to a deficit in 2011. The deterioration in Romania has been particularly severe, equivalent to wiping out all financial assets owned by households. In Australia, the government's net financial position was relatively flat and close to being balanced until 2008, but it has since climbed to 18% of household net financial assets. Relative government debt has grown by 18% in the USA (from 14% to 32%) and by a similar amount in Hungary, Poland, Portugal, Spain and the UK. The rise was slightly higher in Japan (from 28% to 56%), and considerably higher in Ireland (17% to 92%) and Greece (59% to 112%).

## 4.9 Which countries have the greatest problems with government debt?

Among the countries with the highest levels of net government debt relative to household financial assets, the situation in Japan, Poland and Spain appears to be manageable, at least based on the evidence until 2011. In Hungary, government debt rose between 2000 and 2010, almost wiping out the total value of household financial assets, but it pulled back from the brink in 2011. Ireland appears more problematic. Net government debt was close to zero in 2007, but it has since grown at a faster rate than any other country, reaching 92% of household net financial assets in 2011. The equity market in Ireland was buoyant over the past year, which means that the situation may have eased in 2012. However, the overall signs remain worrisome for Irish citizens.

While the problems facing Hungary and Ireland are serious, they pale in comparison to those facing Greece. Household debt in Greece saw an almost six fold increase between 2000 and 2009, and afterwards edged lower to USD 20,400 per adult in 2011. The increase in debt was much faster than growth in financial assets. As a consequence, household debt rose from 12% of financial assets in 2000 to 57% in 2011. Government net debt per adult also increased over the period, rising 190% to USD 53,600 between 2000 and 2009, before declining to USD 32,500 in 2011. Greece is the only country whose net government debt exceeds total household financial assets, and this has been the case every year since 2008. Assigning government debt to households would have resulted in the Greek population having negative financial assets averaging USD 13,000 in 2008–10. While the situation has eased a little since then, it still results in negative net financial assets averaging USD 4,800 in 2011.

## 4.10 Summary

With the regular occurrence of sovereign debt crises, relatively little attention has been given to the parallel issue of personal debt. Yet household debt has transformed over the past 30 years from low-level borrowing mostly securitized on housing assets into wholesale credit seemingly available to anyone for any purpose. As a consequence, household debt as a proportion of

income has doubled almost everywhere, and has on occasion exploded by a factor of ten or more.

Our analysis of household debt highlights a number of facts that may come as a surprise. For example, Canada now has the highest debt to income ratio among G7 countries, and Italy has the lowest. The countries with the highest levels of household debt per adult – Denmark, Norway and Switzerland – are among the wealthiest and most successful; the average debt in Greece, Italy, Portugal and Spain is much lower. Debt has risen significantly in developed countries over the past decade, but it is nowhere near the scale of the developing world, where almost every country has surpassed the global average of 45% growth during 2000-12.

While a high ratio of debt to net worth does not itself signify a problem for a country, it does appear to send a warning signal when combined with rapid growth in household debt. Greece, Hungary and the United Arab Emirates fall within this category and all have had problems with debt in recent years. These problems were not directly related to household debt, but rapid growth in personal debt in a highly indebted country is perhaps indicative of a relaxed credit environment that may have wider implications.

Contagion in the Eurozone links Ireland, Italy, Portugal and Spain with the problems in Greece. Our estimates of household assets and debts suggest that Greece is an outlier among Eurozone countries, and that the other countries are better placed to absorb the rise in government debt. However, the deterioration in Ireland's position since 2008 remains a source of serious concern. Beyond the Eurozone, Hungary and Romania are the countries that need to be most carefully monitored.

## 5. Inheritance of wealth

### 5.1 Introduction

There are positive as well as negative aspects to inheritance from both an economic and a social standpoint. For individuals, it can create opportunity – the opportunity to start a new business or to expand an existing one, the chance to acquire a good education, or the freedom to move in order to pursue a better life for oneself and one's children. Historically, it has given some talented people sufficient free time to be highly creative in the arts or sciences. Inheritors have also founded or supported major charities and public projects, including hospitals, universities, museums, and art galleries. In other words, inheritance can be an important positive force.

Inheritance also has negative connotations. It is often seen as a "birthright lottery," in which lifetime prospects are linked to birth rather than personal choices, effort, and achievement. Andrew Carnegie and others who amassed self-made fortunes feared that the expectation of inheritance might undermine the work ethic and ambition of heirs, and established foundations or made other charitable donations to partly make up for this. Such concerns could weaken the fabric of society if enough people consider the allocation of resources and opportunities to be unfair, or if wealthy offspring are dissolute and irresponsible. The economy may also suffer if an excessive proportion of its industry or finance is in the hands of heirs who lack ambition as opposed to dynamic self-made individuals. If a large proportion of the nation's wealth is inherited, growth prospects could be impaired.

Concerns about the effects of inheritance have had an impact on public policy in connection with public education, progressive taxes and death duties, for example. These concerns also lead to a desire for information on the level and distribution of inherited wealth. Here, we review some of the important research recently undertaken and offer some new evidence on the topic. Much of the empirical evidence has been collected in Europe and North America, but patterns and trends in emerging market and developing countries are also very much of interest.

### 5.2 Evidence on inheritance

Modern economic research on inheritance as a source of wealth began with a study by Wedgwood (1929) who assembled a sample of men in the UK leaving estates worth GBP 10,000 or more in the 1920s. Examining the wills of their parents and other close relatives led him to conclude that about one-third had inherited their fortunes, one-third were self-made, and one-third belonged to an intermediate category. Harbury and co-authors repeated Wedgwood's study for 1956-57, 1965 and 1973 (see Harbury and McMahon, 1973 and other references in Davies and Shorrocks, 2000). They found evidence that the role of inheritance declined in importance for top wealth holders in the UK over the next 50 years. Similar evidence of a reduction in the importance of inheritance from the 1920s to the 1970s has been uncovered in a number of other countries, including France, Sweden, and the USA (see Piketty, 2011, Roine and Waldenstrom, 2009, and Kopczuk and Saez, 2004, respectively).

The "rich lists" published by Forbes magazine and others provide more up-to-date evidence on inheritance. Each year, Forbes provides a list of the world's billionaires and includes

supplementary information, such as whether the billionaire was “self-made.” Table 5-1 summarizes the results for countries with 15 or more billionaires in 2012, as well as for regions and for the world. Of the worldwide total of 1,226 billionaires in 2012, 842 billionaires (or 69%) were reported as self-made. That said, this figure is inflated by China, Russia, and other Eastern European countries, which account for 209 billionaires, only two of whom are not self-made. When these transition countries are excluded, only 62% of billionaires are self-made, with the implication that 38% owe their fortunes partly or wholly to inheritance. The self-made fraction varies greatly across countries – from just 35% in Germany and 40% in France, to 78% in Australia and 86% in the UK. In the USA, which has one-third of the world’s billionaires, 73% are self-made billionaires.

### 5.3 Characteristics of inheritors

There is little to distinguish the relative wealth or age of self-made billionaires compared to those who inherited their fortunes. Excluding transition countries, inheritors average 64 years of age worldwide, while the self-made average 65 years. The average wealth of inheritors, at USD 4.2 billion, is 16% higher than that of the self-made. However, there is considerable variation in these patterns. For example, in France, Japan, and the UK, the inheritors are appreciably *older* than the self-made, while in China and Russia, billionaires are unusually young, averaging just 51 years of age. Assuming typical mortality rates, this suggests slow growth in the number of inheritors among the billionaires in those countries for some time.

Large countries are sometimes representative of their regions or sub-regions, and sometimes they are not. In continental Northern Europe, the percentage of self-made billionaires in France and Germany is similar to the Nordic countries (40% self-made, excluding Norway) and Switzerland (44%); however, in the four other countries in the area with billionaires (Austria, Belgium, the Netherlands and Norway), 74% are self-made billionaires (14 out of 19). The self-made billionaire percentage (60%) in Brazil is fairly close to the figure of 56% for Latin America as a whole. Japan’s percentage of self-made billionaires (75%) is high for the Asia-Pacific region, which (excluding China) has an overall figure of 58%, while India and Indonesia, at 42% and 53% respectively, are on the low side. Finally, in Africa 11 of its 16 billionaires (69%) are self-made, while the Middle East (excluding Israel) is at the opposite extreme with only 25 self-made billionaires out of 57 (44%). Israel differs from its neighbors with 9 self-made billionaires out of 13 (69%).

The percentage of billionaires who are self-made rises with age (Table 5-2). Excluding the transition countries again, it is below 60% for those aged 25–44 or 45–54, but 67% or higher for the age group above 65. This reflects the fact that it takes time to build up a business or investments worth USD 1 billion or more starting from scratch. Inheritors, on the other hand, have had at least one more generation to build up their wealth, and they increase in frequency as wealth rises. The self-made percentage falls from 67% in the Forbes bottom quintile (i.e. bottom 20% group by level of wealth) to 47% for the top 5%. The sole exception is at the very top of the Forbes listing, where the self-made account for eight of the ten wealthiest billionaires. The attention given to self-made people like Bill Gates and Warren Buffett at the apex of the world wealth distribution may create the impression that self-made fortunes become more common among billionaires as wealth rises, but this impression is misleading.

## 5.4 Trends over time

Changes over time in the importance of inheritance at different levels of wealth distribution have not been studied for the world as a whole, but have attracted attention in the USA, which has some of the best data in this respect. There are two main sources: the Federal Reserve's triennial Survey of Consumer Finance (SCF), last conducted in 2010; and the annual Forbes 400 list of the richest Americans. Since the SCF explicitly omits the Forbes 400 group, these two sources complement each other. Roughly speaking, the Forbes 400 covers the billionaires while the SCF covers everyone else.<sup>1</sup>

The SCF asks respondents whether they have received gifts and inheritances, and, if so, their value and when they were received.<sup>2</sup> Wolff and Gittleman (2011) have used those data to chart trends in inheritance from 1989 to 2007. They find that the percentage of families that received a wealth transfer in the form of a bequest or gift fell from 24% in 1989 to 18% in 2001, and subsequently increased to 21% in 2007. Demography provides possible explanations for this U-shaped trend. Over this period, longevity continued to rise in the USA, particularly for males, reducing the number of transfers, since the bulk occurs at death. It may help to explain the decline between 1989 and 2001. The subsequent rise may be partly due to the aging of the large baby-boom cohort, which brought the group into "inheritance range" around the turn of the millennium.

The SCF data also shows that wealth transfers are on average quite large, and that they rise steeply in importance with the level of income or wealth. From 1989 to 2007, they averaged USD 84,700 or 23% of net worth for the overall sample, and USD 408,400 for just those who had received transfers. Of those with income over USD 250,000, 38% had received a transfer, with an average amount of USD 3 million for recipients. For families in the top 1% of wealth distribution, the corresponding numbers were 44% with a transfer and an average amount of USD 5 million. Transfers were more common as well as larger for whites, the better educated and older people. The incidence was 25% for whites, 29% for those with 16 years of schooling (generally a post-secondary education), and 29% for those aged 75 or older.

## 5.5 Incidence of inheritance among the Forbes 400

Another source of data is the "Forbes 400" list of the 400 wealthiest individuals/families in the USA, which currently corresponds almost exactly to the list of US billionaires. In 2012, 69% were self-made billionaires. In 2007 and in some earlier years, additional information on inheritors was provided, with 39% being classified as "inherited and growing" and 61% simply described as having inherited. In the USA – as for the world as a whole – the self-made percentage rises with age, but interestingly this percentage does not fall uniformly with the level of wealth. While 74% of those in the bottom quintile are self-made, the figure drops to an average of 67% for the next two quintiles, and subsequently rises to 68% in the fourth quintile and 70% in the top quintile. The rise in the incidence of the self-made in the higher ranges of

---

<sup>1</sup> The minimum wealth of the Forbes 400 changes from year to year, along with the rise and fall in the fortunes of the super-rich. The cut-off in 2012 was USD 1.05 billion, so the Forbes 400 is currently very close to being the list of US members among Forbes billionaires.

<sup>2</sup> Other surveys have asked similar questions in the United States, as well as in France, Sweden, and the UK (see Klevmarken, 2004, Karagiannaki, 2011a, and Wolff and Gittleman, 2011 for more information). However, the high frequency of the SCF and its long timespan are unusual.

the Forbes 400 list has often been noted and has a popular explanation. In the USA, each generation has entrepreneurs and investors who amass spectacular fortunes and rise to the top of the pyramid. When these "super billionaires" die, their fortunes are not passed on intact, but are divided among widows, children and other beneficiaries. Consequently, the second generation drops down the Forbes 400 list (or drops out altogether), the third generation falls further, and so on.

It is easier for a person to be successful and enter the Forbes 400 list when the economy is growing at a fast pace, business is booming, and asset prices are rising quickly. Although the two decades before the global financial crisis were interrupted by two recessions and associated stock market crashes, overall conditions were conducive to the creation of new fortunes. Self-made billionaires would have been expected to oust inheritors in the Forbes 400 over much of this period, and this appears to have happened.

We use a sample that includes all the members of the Forbes 400 list in 2007, and smaller subsamples for earlier years, dropping a sufficient number of the least wealthy to keep the sample size constant as a percentage of the US adult population. Table 4-3 shows the percentage of Forbes 400 billionaires who inherited their fortunes at certain intervals between 1982 and 2007, both for the group as a whole and split between those who above or below the age of 55 (see also Figure 5-1). The greater incidence of inheritance among younger members is once again evident. There is also a clear downward trend in the incidence of inheritance until the turn of the millennium, then an apparent rebound (as in the SCF data), which could be a random event or due in part to demographics, as suggested in the earlier discussion of the SCF. Between 2000 and 2005, the number of billionaires with inherited fortunes in our Forbes 400 subsample rose by 26, of whom 17 were baby-boomers aged between 40 and 55 from just four families.<sup>3</sup> While there is clearly a degree of randomness involved here, the fact that so many new inheritors were created is partly a reflection of the number of children in these families.

Figure 5-1: Percentage of inherited fortunes by age, 1982-2007

Source: See Table 5-3

<sup>3</sup>The list is made up of two Leners (MBNA credit card company), three Strykers (Stryker Corp, medical supply company), four Johnsons (S.C. Johnson Co., makers of floorwax and other products), and eight Pritzkers (Marmon Co. and Hyatt hotels).

It therefore appears that the arrival of the large baby-boom cohort at “inheritance age” may have swelled the ranks of inheritors at the very top of the distribution, as well as in the SCF population. The fact that changes in business conditions are important, as well as demography, is indicated by the drop in the incidence of inheritance from 22% to 20% between 2005 and 2007. In this short time span, a surge in self-made billionaires, mainly in the financial sector, displaced a number of inheritors in the Forbes 400 list.

## 5.6 What fraction of wealth is inherited?

Various attempts have been made to estimate the percentage of household wealth which is inherited. Kotlikoff and Summers (1981) offered two different methods. One approach – summing the amounts received as gifts or bequests by the current generation – suggested that the present value of inheritances was equal to 46% of current household wealth in the USA. A second exercise, which they considered more reliable but whose results have been more controversial, cumulated past savings out of earnings to yield an estimated 81% of wealth due to inheritance.

The different methods account for the discrepancy between the results. Data on gifts and bequests are based on tax records, and may not be reliable given the strong incentives to minimize the flow of intergenerational transfers that are subject to tax. Various measures are used to do this, one of the most important being the use of family trusts to transmit wealth from generation to generation. The efficacy of the mechanisms is apparent from the low revenues generated by estate and inheritance taxes in whatever country they are applied.

Modigliani (1988) disputed the Kotlikoff-Summers calculation, drawing instead the almost opposite conclusion: that 80% of household wealth was self-accumulated. Three reasons account for the contradictory results. Kotlikoff-Summers assumed that (1) parental expenditures on children’s education should be treated as inheritance; (2) consumer durables are consumption rather than saving; and (3) all interest on inheritances should be assigned to inheritance – the so called “capitalization issue”. Blinder (1988) reviewed the debate, arguing that education transfers should not be included in inheritances and that consumer durables were a form of saving. He concluded that the answer to the question hinged on capitalization. If all interest on inheritances is cumulated with inheritances then 50%–60% of wealth in the United States was inherited; but the ratio would be only 20%–30% if the interest is allocated to lifecycle saving. Davies and Shorrocks (2000) recommended a compromise, pointing out that if the interest is split 50:50 between inheritances and lifecycle saving, then inherited wealth would be 35%–45% of current wealth, a conclusion consistent with the results of about half a dozen leading studies on the issue. Subsequent contributions include Brown and Weisbrenner (2002) and Wolff (2002), who both use SCF data for the United States and conclude that inheritances were 19%–35% and 20%–25% of aggregate wealth respectively. Klevmarken (2004) provides an estimate of 10%–20% for Sweden.<sup>4</sup>

---

<sup>4</sup> Few estimates have been generated since the early 2000s, possibly reflecting the realization that – as argued by Davies and Shorrocks (2000) and others – the wide range of estimates was due to differences in approach that were unlikely to be resolved. A view also seems to have spread at about this time that while the aggregate size of inherited wealth was interesting, it was less interesting than the nature of bequest motives and the impact of inheritance on income and wealth distribution (Dynan et al., 2002; Gale and Potter, 2003).

## 5.7 The share of inherited wealth in various scenarios

The debate concerning the fraction of wealth that is inherited took place largely in the context of the United States and prior to the turn of the century. There is good reason to believe that this fraction varies across countries and over time. To investigate those aspects, we have examined the determinants of the ratio of inherited wealth ( $I$ ) to total wealth ( $W$ ) in a society with constant (but different) rates of return to safe and risky assets, a constant saving rate ( $s$ ) out of “regular” income (earnings plus the normal return to safe assets), a constant rate of consumption out of capital gains (defined as the return to the risky asset minus the “normal” return on safe assets), and constant growth rates of both population and real earnings. In that world, there is a simple relationship between the fraction of inherited wealth ( $I/W$ ) and three key steady state parameters: the annual flow of new inherited wealth as a fraction of self accumulated wealth ( $\pi$ ); the saving rate out of regular income ( $s$ ); and the ratio of total wealth to total earnings,  $\rho = W/E$ , where  $E$  is total earned income. The relationship is:

$$\frac{I}{W} = \frac{\pi}{\pi + s/\rho}$$

One attractive feature of this equation is the ease with which realistic values can be assigned to the three parameters:  $\pi$ ,  $s$ , and  $\rho$ . Parameter  $\rho$  is close to the commonly measured ratio of household wealth to disposable income, since most of disposable income comprises earnings, in advanced countries at least. Shorrocks et al. (2011) report that the long-run ratio of wealth to income averaged 4-6 in G7 countries until the mid 1980s. The ratio has risen more recently in most G7 countries, but still appears to revert to a value of about five in the USA, between bouts of market excess. Considering that the wealth-earnings ratio should be a little above the wealth-income ratio, it seems reasonable to assume  $\rho = 6$  for developed economies in the late-1900s, and  $s = 10\%$  as representative of the savings rate in developed economies during the same historical period. Finally, with a generation typically lasting about 30 years, around  $1/30^{\text{th}}$  of wealth should be inherited each year. Thus, allowing for the fact that part of this inheritance derives from inherited rather than accumulated wealth,  $\pi = 2\%$  appears reasonable.

Table 5-4 shows steady-state values of  $I/W$  generated by different values of  $\rho$ ,  $s$  and  $\pi$ , where for each of the latter we consider a range of parameter values that include our “best guess” steady-state values for advanced economies in the 20<sup>th</sup> century. Those central values generate  $I/W = 54.5\%$ , which is in the middle of the range that Blinder (1988) found plausible for the USA with full capitalization of inheritances (which is implicit in the steady-state model considered here). Alternative sets of parameter values for  $\rho$ ,  $s$  and  $\pi$  allow us to speculate on what is likely to happen in a variety of stylized hypothetical societies.

**A:** *Low-growth traditional society* ( $\rho = 7$ ,  $s = 5\%$ ,  $\pi = 3\%$ ;  $I/W = 78.3\%$ )

Pre-industrial societies before demographic transition – pre-modern Europe or India before the 19<sup>th</sup> century are typical examples here. Low or zero population and earnings growth makes high wealth relative to income likely since the wealthier older generation is relatively more important – both in population and economic terms – than in higher-growth scenarios. Poorly developed financial institutions and poverty generate a low saving rate ( $s$ ), while a high mortality rate leads to a relatively high annual rate of flow of new inherited wealth ( $\pi$ ). The result is a very high  $I/W$ , possibly reinforcing social and economic stagnation. (Consistent with our analysis, De Long, 2001, estimates  $I/W$  equal to 91% for pre-industrial Eurasia.)

**B: *Slow-growing less-developed country*** ( $\rho = 5$ ,  $s = 5\%$ ,  $\pi = 2\%$ ;  $I/W = 66.7\%$ )

Most countries in Asia, Africa and Latin America were former examples of this type of society and some (Myanmar, Ethiopia, Paraguay, Bolivia...) still are – going through demographic transition but still having low savings and low income growth. Fast population growth makes the elderly relatively unimportant, reducing mean wealth relative to mean income and producing a lower  $\rho$  than in a developed economy. The saving rate in a low-growth less-developed country (LDC) is still low – we assume that the rate is the same as in a low-growth traditional society. The rate of flow of new inheritances is lower than in the traditional society due to the lower mortality rate:  $\pi = 2\%$  illustrates this. The lower  $I/W$  ratio than in the traditional society indicates some grounds for optimism regarding future growth prospects, as self-accumulated wealth displaces inherited wealth to some extent.

**C: *Miracle economy*** ( $\rho = 4$ ,  $s = 20\%$ ,  $\pi = 1\%$ ;  $I/W = 16.7\%$ )

The wealth-income ratio is low, the saving rate is high, and the annual flow of inherited wealth is low, reflecting the dominant population and economic weight of the young when both population and income grow quickly. This contrasts sharply with the traditional society or low-growth LDC. These parameter values would generate a very low  $I/W$  ratio if they persisted into a steady state. Germany and Japan, and afterwards the Asian Tigers, each passed through the miracle economy phase in about three decades, i.e. very quickly. Thus, while the  $I/W$  likely fell in the miracle phases of these economies, we doubt if it fell into the 17% region predicted here for an economy in a “permanent miracle.” On the other hand, the latest miracle economy, China, started out with an  $I/W$  (at least officially) of zero because it emerged from a society without any significant private property ownership or inherited wealth. The  $I/W$  has likely been rising slowly and should still be below the steady-state miracle level. If we also consider that China’s saving rate has probably exceeded that of previous miracle economies, it appears that  $I/W$  must indeed be low in China today.

**D: *Low-growth advanced economy*** ( $\rho = 8$ ,  $s = 5\%$ ,  $\pi = 3\%$ ;  $I/W = 82.8\%$ )

Shorrocks et al. (2011) shows that, with the exception of the USA, there has been an upward trend in wealth-income ratios in most G7 countries since the mid-1980s, with values as high as 9 observed in Japan and the UK. At the same time, household saving rates have declined to levels around 5% or lower.

Piketty (2011) estimates that the flow of inherited wealth in France has risen from about 5% of GDP in the 1950s to 15% today, implying a large increase in  $\pi$ . A similar but smaller increase (from 3.0% in 1984 to 4.3% in 2005) has also been noted for the UK: see Karagiannaki, 2011a. Table 5-4 shows that these changes result in a much higher steady-state level of  $I/W$ , as Piketty (2011) has emphasized. This could be the future for all advanced countries, although hopefully France is an outlier along with Germany, as suggested by the earlier evidence on the fraction of self-made billionaires, in which case the scenario may be limited to a small number of nations.

## 5.8 Inequality Impacts of Inheritance

The impact of inheritance on wealth inequality has been hotly debated for a long time. Distributional effects were particularly worrisome when primogeniture – the tradition of passing the bulk of personal wealth to the eldest son – was still prevalent. Nowadays there are important forces that tend to reduce the disequalizing impact of inheritance. One is more equal division of estates. In high income Western nations it is now common to divide estates equally among

offspring. If children always married spouses from equally wealthy families and if the rich did not have too many children, then high concentration of inherited wealth could be maintained in the face of this equal division. However, while the correlation of the parental wealth of spouses is high, it is far from perfect, so that equal estate division tends to reduce the concentration of *inherited* wealth over time. This tendency does not result in a continuous decline in overall wealth inequality, since it is offset by differences in self-accumulated wealth.

Although it has been understood for a long time that estate division and the recombination that occurs through marriage tend to break down wealth concentration, the view that inheritance increases inequality is still widely held and seems intuitive. It was challenged, however, by Becker and Tomes in a series of papers exploring the altruistic model of bequests (Becker and Tomes, 1979; Tomes, 1981). In this model parents care about their children's welfare and give larger transfers to their lower-earning offspring. As shown by Davies (1986), this can reduce lifetime income inequality in long-run equilibrium. However, the "compensatory bequests" predicted by Becker and Tomes are not commonly observed: equal division of estates on death is the general rule (Light and McGarry, 2004, and Kopczuk and Lupton, 2007). While such compensatory behavior has been found for inter-vivos *gifts*, (see e.g. Cox and Rank, 1992, and Dunn and Phillips, 1997), the flow of bequests is considerably larger than that of gifts. Intergenerational transfers may be more benign than generally expected, but it is doubtful that they are equalizing overall.

Davies (1982) reports a simulation study of the distribution of income and wealth for Canadian households that incorporates Becker-Tomes altruistic bequests, but with the stipulation that parents cannot leave negative bequests to their children – a feature that is implicitly present in most theoretical treatments, but which is of questionable realism. With this restriction, bequests strongly increase the shares of the top 1, 5, and 10% in personal wealth. Gokhale et al. (2001) also obtain a disequalizing effect on wealth in a simulation model that incorporates more real-world features, such as differential fertility and social security.

Other theoretical perspectives also challenge the Becker-Tomes idea of equalizing bequests. Bernheim et al. (1985) presented a model of strategic bequests, in which parents elicit attention from their children based on the promise of an eventual bequest. Here, and in voluntary exchange models as well, bequests may be disequalizing in part because larger amounts may be given to children with higher wage rates, who charge a higher "price" for attention (see Davies, 1996).

Wolff and Gittleman (2011) have recently revived the idea that inheritance may reduce wealth inequality by showing that in both the SCF and PSID surveys in the United States, inherited wealth equalizes the distribution of household wealth in an accounting sense. When past inheritances are cumulated at a market rate of interest (3% is assumed), on average their present value is a larger percent of observed household net worth at lower wealth levels. As shown by Joulfaian (2006) and others, however, receiving an inheritance has a negative effect on self-accumulation. If that effect is larger at lower income and wealth levels, one could get the Wolff and Gittleman result even if inheritances went disproportionately to people with higher lifetime income or wealth.

## 5.9 Conclusion

While inheritance creates opportunity for some, it is not *equal* opportunity and there may be other deleterious effects, e.g. on the work ethic and enterprise of the offspring who inherit and on the dynamism of economies with a high ratio of inherited wealth to total wealth. The latter aspects naturally lead to concerns about the level and distribution of inherited wealth. The evidence suggests that over much of the 20<sup>th</sup> century – until the 1970s – inherited wealth became relatively less important and more equally distributed in developed countries. If we consider the situation at the moment in the world, 69% of Forbes billionaires are self-made, and if we exclude China, Russia and the other transition countries, the figure is still 62%. In the USA, the percentage of Forbes 400 billionaires who inherited a fortune fell from 30%–35% in the early-1980s to 20%–22% in the mid-2000s. However, the latest evidence from the United States shows that the incidence of inheritance hit a low point at about the turn of the millennium and afterwards increased. The flow of inherited wealth has also risen somewhat in the UK. And there has been a large increase in the annual flow of new inheritances in France. These changes suggest that the importance of inheritance may be on the rise, a conclusion that is reinforced by our calculations, which indicate the combination of lower savings and a higher wealth-income ratio seen in many advanced economies in recent years are predictors of a higher ratio of inherited to total wealth in the future.

Claims have been made that, overall, as much as 80% of current wealth is inherited, but those claims rest on full capitalization of past inheritances. “Middle of the road” assumptions suggest that inherited wealth likely accounts for 30%–50% of total household wealth in OECD countries. In low-growth or traditional societies the share is likely to be higher. At the other extreme, very little household wealth in today’s transition economies was inherited, unless one treats those who purchased public assets at bargain prices as having “inherited” from the state.

Some academics have challenged the intuitive assumption that inheritance leads to greater inequality. Models with an altruistic bequest motive can lead to inheritances equalizing the long-run distribution of lifetime wealth because parents give more to their lower-earning children. However, these models allow parents to leave debts to their children, which is illegal in most countries; and they predict that estates will usually be unequally divided, contrary to what is observed. While the “equalizing inheritances” school of thought has some empirical support, we believe that the equalizing effect is more apparent than real. Parental transfers may be helpful in mitigating hardship for some low-earning children, but the disequalizing effect of large bequests from wealthier parents is likely to dominate the overall impact.

If inherited wealth and the associated wealth inequality are viewed with concern, there are steps beside inheritance taxation that governments and the wealthy themselves can take to reduce or offset undesirable effects. For example, the wealthy can be encouraged through appropriate tax deductions or credits to increase the large-scale charitable donations they already make. Governments and business leaders can strive to maintain a level playing field so that unjustified wealth inequalities are avoided in the first place. They can also work to ensure that ordinary people have the tools to accumulate assets too. Such initiatives should be broadly acceptable and can help reduce the inequality in both wealth and inheritance.

**Table: 5-1: Forbes billionaires by inheritance status and other characteristics (2012, selected countries)**

Country <sup>1</sup>	All billionaires				Not self-made billionaires

## 6. Composition of wealth portfolios

### 6.1 Financial versus non-financial assets

We look first at the relative importance of financial versus non-financial assets in the average household portfolio. Expressed as a percentage of gross household assets, the pattern clearly differs markedly between poorer and richer countries and regions, as can be seen in Table 6-1, which shows the breakdown for the countries where we have the best data. In developing countries, for example India and Indonesia, it is not unusual for 80% or more of total assets to be held in the form of non-financial assets, including housing, farms, and small business assets. This pattern is also associated with the relative under-development of financial institutions in many lower income countries.

A high proportion of real property is also evident in our results for transition countries in Europe, although it should be noted that except in the case of the Czech Republic non-financial assets for these countries are fairly rough estimates. From Table 6-1 we see that non-financial assets exceed financial assets in all the European transition countries shown, and that the difference is generally large. As in developing countries this difference reflects in part the state of the financial sector, but also the large scale privatization of housing that occurred in these countries in the 1990s. The influence of the latter factor shows up in the fact that financial assets are largest relative to non-financial assets in the countries where privatization was less complete, such as the Czech Republic (see Lux, 2006).

As countries develop, and also as they make the transition to a market economy, the importance of non-financial assets tends to decline. An interesting example is provided by China, where the share of financial assets in 2012 is 47%. Another example is provided by Singapore, a country much further along the development path, but still nevertheless seeing the share of financial assets in household portfolios continuing to rise – from 43% in the year 2000 to 47% in 2012. In the richest countries, financial assets typically account for more than half of household wealth. An important example here is the USA, where about two thirds of household assets were in financial form in 2012.

There are interesting exceptions to this general pattern. Robust house price rises drove the share of non-financial assets above 60% in France and Italy by 2012. The share of non-financial assets also rose in the UK, from 44% in the year 2000 to 55% in 2007. (Despite the post-2007 fall of house prices, the share of non-financial assets remains unusually high in these countries since stock prices also fell.) And in the developing world South Africa is a strong outlier, having an exceptionally high share of financial assets: the share of 70% in 2012 exceeds that found in both the United States and Japan. This high share reflects on the one hand, the advanced development of South Africa's financial institutions including its private pensions, and on the other hand, relatively low house prices.

### 6.2 Financial assets: Equities, bonds or cash?

Table 6-2 provides more detail for selected countries, showing the breakdown of financial assets into three categories: currency and deposits ("liquid assets"); equities (all shares and other equities held directly by households); and other financial assets. In most countries the reserves of life insurance companies and pension funds form the largest component of "other financial assets" – these reserves of course include equities and other financial assets that are in effect being held on behalf of the household sector.

The composition of financial assets differs considerably across countries, especially with regard to the importance of equities. One interesting trend we note is that equities held directly are not always a large component of household financial wealth, even in countries with very active financial markets. In the UK and Japan, for example, equities account for just 15% and 7% of total financial assets respectively. In contrast, they make up 37% and 44% of financial assets in Sweden and the USA, respectively. To calculate the overall percentage of the household portfolio held in equities, equities held indirectly via insurance policies and pension plans would need to be added to the total of equities held directly. However, this is not possible since available household balance sheet data do not show the composition of assets held in insurance and pension reserves. If the purpose were to find out the total exposure of the household sector to stock market risk, it is also not clear that this exercise would provide the answer. Households have explicit or implicit guarantees on their rights to insurance and pension benefits, so that the risk characteristics of the latter are not the same as those of the assets held in the reserves.

Broadly speaking, the relative importance of currency and deposits falls as that of bonds and equities increases. On the other hand, the portfolio share of "other financial assets" does not vary greatly, typically staying in the range of 40%–45%. However, when we come to the UK, Japan and Colombia, which have the lowest portfolio share of equities, the pattern breaks down. The UK has a moderate currency and deposits share, but the largest "other financial assets" share, reflecting large life insurance and pension reserves. Colombia also has more in the form of "other financial assets" than typical. Japan, on the other hand, which has a strong tradition of saving in deposit form, has a very large currency and deposits share and only a 39% share of "other financial assets."

### 6.3 The impact of the financial crisis

In the light of the global financial crisis, it is interesting also to examine how the overall composition of personal wealth and in particular the proportion of financial assets to total household assets has changed over the past decade. A decline in the relative importance of financial assets was seen in a number of countries in 2008, for example in Denmark, Italy, Sweden, Switzerland and notably China. In other countries, the credit crisis depressed both property prices and share values, so the share of financial assets is more stable; little change was seen in 2008 in the share of financial assets in the USA, Spain, the UK and Japan. In a few countries, such as Germany, the relative size of financial assets actually increased in 2008.

Longer term, the share of financial assets does not often appear to have changed dramatically. In France, a decade of strong property price increases has reduced the share from 45% to 35%, and a somewhat similar effect is seen in Italy, where the share fell from 47% to 38%. Elsewhere, however, effects generally seem to be mostly short-term. The USA showed a relative decline in financial assets from 2000 to 2005, for example, but then with a booming stock market the share rebounded until brought to a halt by the global financial crisis. The net outcome is that from 2000 to 2012 the share of financial assets in household portfolios in the USA fell from 71% to 68%, but it would not be safe to identify this as reflecting a long-term trend. Japan shows a rise in the proportion of financial assets during 2000–2006, a decline during the financial crisis, and a subsequent increase; the share is now back to the level of 2007. Amongst developing nations, the trend in the financial asset share in India is almost flat, but the trend is upwards in Indonesia, with a noticeable increase during the last 3 years.

### 6.4 Conclusion

The composition of household balance sheets is an important determinant of trends in consumption and investment, and in many ways reflects the financial development of individual countries. For instance, debt as a proportion of total household assets tends to be low in developing and some transition countries because financial intermediation and property rights are underdeveloped, while debt levels in OECD countries are relatively high, reflecting a more developed financial system.

Our analysis of household balance sheets examines financial and non-financial assets and debt from a global perspective. In general, non-financial assets like housing, land, and small business assets make up a relatively large proportion of household wealth in the developing world and in transition countries. They have also come to the fore in countries like France and Italy over the last decade where house prices have risen steadily and more quickly than prices of financial assets. In contrast, financial assets form a large proportion of the household balance sheets in countries like the USA, Japan and Switzerland.

Table 6-1: Assets and debts as percentage of gross household wealth for selected countries by year

## 7. Region and country focus

### 7.1 Introduction

Countries differ greatly in the level and pattern of wealth holdings. There are also distinct differences at the regional level. It is therefore interesting to compare regional variations and trends during the past decade, and to document the variety of country circumstances and experiences.

While data quality is generally good in the rich countries that hold most of the world's wealth, it is usually questionable elsewhere. The countries discussed in this section are all interesting in their own right. But another reason for selection is that they all have data on the mean level of household wealth and a reasonable way to estimate the distribution of wealth across the population.

The accompanying tables collate information on wealth holdings for each of the regions and countries. Some of the core data is summarized in Table 7-1. Table 7-2 reports wealth per adult measured in current US dollars and also converted using the average USD exchange rate over the 13-year period, while Table 7-3 provides similar information for aggregate household wealth measured in trillion US dollars. Table 7-4 shows the composition of wealth for the most recent year for which figures are available. For each region and country, the wealth share of each decile and top percentiles is recorded in Tables 7-5 along with the minimum wealth needed to belong to a given regional wealth quantile. Finally, Table 7-6 shows the distribution of the adult population by wealth range.

### 7.2 Mean wealth 2000–12

Three charts are provided for each of the regions. Figure 1 plots two series for mean wealth over 2000–12, one measured in current US dollars and the second converted by the average USD exchange rate. The global level of wealth per adult – which amounted to USD 49,000 in 2012 – masks considerably regional variation. The average for Northern America in 2012 was USD 259,000 compared to approximately USD 120,000 in Europe, USD 47,000 in the Asia-Pacific region (excluding China and India), USD 22,000 in Latin America and USD 4,500 in Africa.

All regions recorded an increase in wealth per adult during the last decade. Growth in the Asia-Pacific region has been subdued, with average wealth rising 23% between 2000 and 2007 and then flattening out until 2010: when measured in local currencies, mean wealth increased only 14% over the 13 year period. This is due mainly to the modest performance of Japan, which accounts for 55% of the region's total wealth. In contrast, average wealth more than doubled in Latin America. Although wealth levels in other regions still remain far below those in Europe and Northern America, particularly in Africa and India, the regional imbalance appears to be eroding over time. Africa, Latin America, India, and particularly China, all increased their share of world wealth between 2000 and 2012. This seems to be a long term phenomenon due in part to higher population growth, but reinforced in the last four years by the impact of the financial crisis, which hit the developed world more severely.

The relative stability of the US economy has led to an appreciation of the USD against most currencies during the past year. As a consequence, although total global household wealth increased slightly at constant USD exchange rates, it fell 5.2% in current dollar terms to USD 223 trillion, the first decline since the financial crisis of 2007–08 (see Table 7-3). Most regions

and countries have experienced depreciating currencies, but the impact is especially apparent in Europe, raising the aggregate wealth loss to USD 10.9 trillion, by far the largest contribution to the total global loss of USD 12.3 trillion. Asia-Pacific (excluding China and India) was the other big regional loser, shedding USD 1.3 trillion. Other losses in Africa, India and Latin America countries were offset by modest gains in North America (USD 880 bn) and China (USD 560 bn), which had a relatively quiet year in comparison with recent history which has seen wealth in China grow by 13% per annum since the year 2000. The latest wealth estimates indicate that by mid-2011 all regions except Africa had fully recovered from the financial crisis, but Europe and India have now dipped back below the level achieved in 2007.

Expressed in percentage terms, Europe and India both suffered double digit wealth losses between 13% and 18%. Rising adult populations – which grew by 1.5% worldwide – caused wealth per adult to decline even more. In North America the larger number of adults offset the increase in total wealth, to leave China as the only region where wealth per adult rose significantly. The large percentage decline recorded for India reflects the relatively low asset base and is distorted by adverse exchange rate movements. When valued in rupees, household wealth in India experienced modest positive growth, rising by 2.8% over the past year in aggregate, and by 0.6% per adult. As might be expected given encouraging economic indicators in recent years, the underlying performance was even better in Africa, amounting to 5.7% growth of total wealth in constant dollars and to 2.9% growth of wealth per adult.

### 7.3 Components of personal wealth

Figure 2 for each region displays the breakdown of wealth per adult into financial and real (non-financial) forms, as well as the average level of debt. On average internationally, financial assets and non-financial assets each comprise about half of gross assets in 2012, and debts amount to 15%. Financial assets are more important in several countries, most notably Japan and the United States, where they represent more than 60% of gross assets. In developing regions, non-financial assets typically account for the bulk of household wealth: they form 61% of gross assets in Latin America and almost 85% of assets in India, for example. The proportion of real assets is also high in Indonesia, and in several rich countries including Australia and France, driven in part by recent rises in house prices.

A systematic link with the stage of development is also evident in the level of household debts expressed as a percentage of gross assets. The share is 4% in India, 12% in Latin America, and 9% in Africa, but rises to 15% in the Asia-Pacific region, 16% in Europe, and 18% in Northern America.

### 7.4 Wealth distribution

Figure 3 for each region shows wealth distribution. Some interesting contrasts between regions are evident. More than 90% of adults in Africa own less than USD 10,000, and 95% of adults in India fall in this range. But the fraction is 47% in Europe, 32% in North America and, 60% in China. On the other hand, almost 24% of adults in Europe and 35% in Northern America have wealth above USD 100,000. The wealth distribution in both Latin America and the Asia-Pacific region closely resembles the pattern in the world as a whole, and both regions show more than 60% of all adults owning less than USD 10,000.

Amongst developed countries, there is substantial variation in the percentage of adults recorded in the lowest wealth ranges. Some countries report significant numbers of people in this category, while others show very few. This reflects such factors as availability of credit including student loans, as well as how many young adults live separately from their parents, making their low wealth more apparent in the survey returns.

## About the authors

**Anthony Shorrocks** is Director of Global Economic Perspectives Ltd. After receiving his PhD from the London School of Economics (LSE), he taught at the LSE until 1983, when he became Professor of Economics at Essex University, serving also as Head of Department and Director of Economic Research for the British Household Panel Study. In 2001 he was appointed Director of the World Institute for Development Economics Research of the United Nations University (UNU-WIDER) in Helsinki where he remained until 2009. He has published widely on income and wealth distribution, inequality, poverty and mobility and was elected a Fellow of the Econometric Society in 1996. Publications include "The age-wealth relationship: A cross section and cohort analysis" (Review of Economics and Statistics 1975), "The portfolio composition of asset holdings in the United Kingdom" (Economic Journal 1982), and, with Jim Davies and others, "Assessing the quantitative importance of inheritance in the distribution of wealth" (Oxford Economic Papers 1978), "The distribution of wealth" (Handbook of Income Distribution 2000), "The world distribution of household wealth" in Personal Wealth from a Global Perspective (Oxford University Press 2008), "The global pattern of household wealth" (Journal of International Development 2009) and "The Level and Distribution of Global Household Wealth" (Economic Journal 2011).

**Jim Davies** is a Professor in the Department of Economics at the University of Western Ontario in Canada, where he has been a faculty member since 1977 and served as chair of the department from 1992 to 2001. He has been the director of the Economic Policy Research Institute at UWO since 2001. Jim received his PhD from the London School of Economics in 1979. He recently completed a five-year term as managing editor of Canadian Public Policy. From 2006 to 2008, he directed an international research program on household wealth holdings at UNU-WIDER in Helsinki and edited the resulting volume, "Personal Wealth from a Global Perspective" (Oxford University Press 2008). He has authored two books and over 60 articles and chapters in books on topics ranging from tax policy to household saving and the distribution of wealth. Publications include "The Relative Impact of Inheritance and Other Factors on Economic Inequality" (Quarterly Journal of Economics 1982), "Wealth and Economic Inequality" (Oxford Handbook of Economic Inequality, Oxford University Press, 2009), and several publications on wealth authored jointly with Anthony Shorrocks and others.

**Rodrigo Lluberás** is a PhD candidate in Economics at Royal Holloway College, University of London and a visiting scholar at the Institute for Fiscal Studies. He holds an MSc in Economics from University College London and a BA in Economics from Universidad de la República, Uruguay. Prior to undertaking his MSc, he worked for three years as an economic analyst at Watson Wyatt Global Research Services and more recently as a research assistant at NESTA. His main areas of expertise are pensions, consumption and wealth.
